45 Cellular Respiration In Detail Study Answer Key 45 Cellular Respiration in Detail Study Answer Key Cellular respiration is a fundamental process that occurs in all living organisms converting chemical energy stored in organic molecules primarily glucose into a form usable by the cell adenosine triphosphate ATP This process is crucial for life providing the energy necessary for various cellular functions including biosynthesis muscle contraction nerve impulse transmission and maintaining body temperature This detailed study answer key will explore the intricate mechanisms of cellular respiration encompassing its four main stages glycolysis the transition reaction the Krebs cycle and the electron transport chain We will examine the specific reactions energy yields and regulatory mechanisms involved in each stage along with their interconnectedness to provide a comprehensive understanding of this vital metabolic process 1 Glycolysis Breaking Down Glucose Glycolysis meaning sugar splitting is the initial stage of cellular respiration occurring in the cytoplasm of all living cells It involves the breakdown of a sixcarbon glucose molecule into two threecarbon pyruvate molecules This process is anaerobic meaning it doesn't require oxygen a Key Reactions and Products Investment Phase Two ATP molecules are invested to activate the glucose molecule resulting in the formation of fructose16bisphosphate Payoff Phase The sixcarbon molecule is split into two threecarbon molecules glyceraldehyde3phosphate This molecule is then oxidized and phosphorylated generating NADH and ATP Ultimately each glucose molecule yields two pyruvate molecules two ATP molecules and two NADH molecules b Energy Yield Net production 2 ATP 4 ATP produced 2 ATP consumed Reduction product 2 NADH 2 c Regulation Glycolysis is regulated at key steps by Phosphofructokinase1 PFK1 This enzyme catalyzes the commitment step converting fructose6phosphate to fructose16bisphosphate and is inhibited by ATP and citrate Pyruvate kinase This enzyme catalyzes the final step of glycolysis converting phosphoenolpyruvate to pyruvate and is inhibited by ATP and acetylCoA 2 Transition Reaction Linking Glycolysis to the Krebs Cycle The transition reaction also known as the pyruvate oxidation occurs in the mitochondrial matrix and bridges the gap between glycolysis and the Krebs cycle In this stage pyruvate is converted into acetylCoA a molecule that enters the Krebs cycle a Key Reactions and Products Decarboxylation Pyruvate loses a carbon atom as carbon dioxide CO₂ Oxidation Pyruvate is oxidized reducing NAD to NADH AcetylCoA formation The remaining twocarbon fragment combines with coenzyme A to form acetylCoA b Energy Yield Reduction product 1 NADH per pyruvate molecule 2 NADH per glucose molecule 3 Krebs Cycle Citric Acid Cycle Generating ATP and Reducing Power The Krebs cycle named after its discoverer Hans Krebs takes place in the mitochondrial matrix It is a cyclical series of reactions that oxidizes acetylCoA producing ATP NADH FADH₂ and CO₂ a Key Reactions and Products AcetylCoA entry AcetylCoA enters the cycle by combining with oxaloacetate to form citrate citric acid Oxidation and decarboxylation The cycle involves a series of oxidation and decarboxylation reactions generating reducing power in the form of NADH and FADH₂ as well as releasing CO₂ Regeneration of oxaloacetate The cycle ultimately regenerates oxaloacetate allowing for the continuation of the process b Energy Yield 3 Direct ATP production 1 ATP per acetylCoA 2 ATP per glucose molecule Reduction products 3 NADH and 1 FADH₂ per acetylCoA 6 NADH and 2 FADH₂ per glucose molecule c Regulation The Krebs cycle is regulated at key steps by Citrate synthase This enzyme catalyzes the condensation of acetylCoA with oxaloacetate and is inhibited by ATP and NADH Isocitrate dehydrogenase This enzyme catalyzes the oxidative decarboxylation of isocitrate and is activated by ADP and NAD and inhibited by ATP and NADH ketoglutarate dehydrogenase This enzyme catalyzes the oxidative decarboxylation of ketoglutarate and is inhibited by ATP NADH and succinylCoA 4 Electron Transport Chain Oxidative Phosphorylation The electron transport chain is the final stage of cellular respiration occurring in the inner mitochondrial membrane It utilizes the reducing power generated in the previous stages NADH and FADH₂ to drive the synthesis of ATP through oxidative phosphorylation a Key Reactions and Products Electron transfer Electrons from NADH and FADH₂ are passed along a series of electron carriers each at a slightly lower energy level releasing energy in the process Proton pumping The energy released during electron transport is used to pump protons H from the mitochondrial matrix across the inner membrane into the intermembrane space creating a proton gradient ATP synthesis Protons flow back across the membrane through ATP synthase a protein complex that harnesses this energy to drive the phosphorylation of ADP to ATP b Energy Yield ATP production The electron transport chain and oxidative phosphorylation generate approximately 32 ATP molecules per glucose molecule with a theoretical maximum of 38 ATP However the actual yield can vary depending on factors like the efficiency of the proton gradient and the energy required for transport processes c Regulation The electron transport chain is regulated by Oxygen availability Oxygen is the final electron acceptor in the chain Its presence is crucial 4 for the continuous flow of electrons ATP levels High levels of ATP inhibit the electron transport chain by reducing the proton gradient 5 Overall Energy Yield of Cellular Respiration Cellular respiration is an incredibly efficient process converting the chemical energy stored in glucose into a readily usable form of energy ATP Glycolysis 2 ATP 2

NADH Transition reaction 2 NADH Krebs cycle 2 ATP 6 NADH 2 FADH₂ Electron transport chain 32 ATP Total ATP yield 38 ATP per glucose molecule theoretical maximum 6 Anaerobic Respiration and Fermentation In the absence of oxygen cells can still obtain energy through anaerobic respiration or fermentation These processes differ from aerobic respiration in their electron acceptors and energy yields Anaerobic respiration Uses alternative electron acceptors such as nitrate or sulfate instead of oxygen This process generates less ATP than aerobic respiration but allows for energy production in the absence of oxygen Fermentation Occurs when oxygen is unavailable and involves the regeneration of NAD from NADH by reducing pyruvate to lactate lactic acid fermentation or ethanol alcoholic fermentation This process yields a much lower amount of ATP than aerobic respiration and results in the production of byproducts that can accumulate in the cells 7 Importance of Cellular Respiration Cellular respiration is crucial for life providing the energy needed for a multitude of cellular processes including Biosynthesis The energy from cellular respiration is used to build complex molecules such as proteins lipids and nucleic acids Muscle contraction ATP provides the energy needed for muscle fibers to contract and relax Nerve impulse transmission ATP is used to maintain the membrane potential of nerve cells and to transmit nerve impulses Active transport Cellular respiration provides energy for active transport mechanisms that move molecules against their concentration gradients 5 Maintaining body temperature The metabolic processes involved in cellular respiration generate heat which helps to maintain body temperature in warmblooded animals Conclusion Cellular respiration is a complex but highly efficient process that fuels life on Earth Understanding its intricate mechanisms from the breakdown of glucose in glycolysis to the final ATP production in the electron transport chain is essential for appreciating the delicate balance of life and the interconnectivity of biological systems This study answer key has provided a comprehensive overview of cellular respiration highlighting its importance in energy production metabolism and overall cellular function
