convex optimization is more popular than ever with extensive applications in statistics machine learning and engineering nesterov introduced optimal first order methods for large scale convex optimization in the 1980s and extremely fast interior point methods for small to medium scale convex optimization emerged in the 1990s today there is little reason to prefer modelling with linear programming over convex programming for computational reasons nonetheless there is room to improve the already sophisticated algorithms for convex optimization the thesis makes three primary contributions to convex optimization first the thesis develops new near optimal barriers for generalized power cones this is relevant because the performance of interior point methods depends on representing convex sets with small parameter barriers second the thesis introduces an intuitive first order method that achieves the best theoretical convergence rate and has better performance in practice

than nesterov's method the thesis concludes with a framework for reformulating a convex program by interchanging the objective function and a constraint function the approach is illustrated on several examples

it was in the middle of the 1980s when the seminal paper by kar markar opened a new epoch in nonlinear optimization the importance of this paper containing a new polynomial time algorithm for linear optimization problems was not only in its complexity bound at that time the most surprising feature of this algorithm was that the theoretical prediction of its high efficiency was supported by excellent computational results this unusual fact dramatically changed the style and directions of the research in nonlinear optimization thereafter it became more and more common that the new methods were provided with a complexity analysis which was considered a better justification of their efficiency than computational experiments in a new rapidly developing field which got the name polynomial time interior point methods such a justification was obligatory after almost fifteen years of intensive research the main results of this development started to appear in monographs 12 14 16 17 18 19 approximately at that time the author was asked to prepare a new course on nonlinear optimization for graduate students the idea was to create a course which would reflect the new developments in the field actually this was a major challenge at the time only the theory of interior point methods for linear optimization was polished enough to be explained to students the general theory of self concordant functions had appeared in print only once in the form of research monograph 12

convex optimization is widely used in many fields but is nearly always constrained to problems solved in a few minutes or seconds and even then nearly always with a human in the loop the advent of parser solvers has made convex optimization simpler and more accessible and greatly increased the number of people using convex optimization most current applications however are for the design of systems or analysis of data it is possible to use convex optimization for real time or embedded applications where the optimization solver is a part of a larger system here the optimization algorithm must find solutions much faster than a generic solver and often has a hard real time deadline use in embedded applications additionally means that the solver cannot fail and must be robust even in the presence of relatively poor quality data for ease of embedding the solver should be simple and have minimal dependencies on external libraries convex optimization has been successfully applied in such settings in the past however they have usually necessitated a custom hand written solver this requires significant time and expertise and has been a major factor preventing the adoption of convex optimization in embedded applications this work describes the implementation and use of a prototype code generator for convex optimization cvxgen that creates high speed solvers automatically using the principles of disciplined convex programming cvxgen allows the user to describe an optimization problem in a convenient high level language then receive code for compilation into an extremely fast robust embeddable solver

known computational error to find out what an approximate solution can be obtained and how many iterates one needs for this the main difference between this new book and the 2016 book is that in this present book the discussion takes into consideration the fact that for every algorithm its iteration consists of several steps and that computational errors for different steps are generally different this fact which was not taken into account in the previous book is indeed important in practice for example the subgradient projection algorithm consists of two steps the first step is a calculation of a subgradient of the objective function while in the second one we calculate a projection on the feasible set in each of these two steps there is a computational error and these two computational errors are different in general it may happen that the feasible set is simple and the objective function is complicated as a result the computational error made when one calculates the projection is essentially smaller than the computational error of the calculation of the subgradient clearly an opposite case is possible too another feature of this book is a study of a number of important algorithms which appeared recently in the literature and which are not discussed in the previous book this monograph contains 12 chapters chapter 1 is an introduction in chapter 2 we study the subgradient projection algorithm for minimization of convex and nonsmooth functions we generalize the results of noce and establish results which has no prototype in noce in chapter 3 we analyze the mirror descent algorithm for minimization of convex and nonsmooth functions under the presence of computational errors for this algorithm each iteration consists of two steps the first step is a calculation of a subgradient of the objective function while in the second one we solve an auxiliary minimization problem on the set of feasible points in each of these two steps there is a computational error we generalize the results of noce and establish results which has no prototype in noce in chapter 4 we analyze the projected gradient algorithm with a smooth objective function under the presence of computational errors in chapter 5 we consider an algorithm which is an extension of the projection gradient algorithm used for solving linear inverse problems arising in signal image processing in chapter 6 we study continuous subgradient method and continuous subgradient projection algorithm for minimization of convex nonsmooth functions and for computing the saddle points of convex concave functions under the presence of computational errors all the results of this chapter has no prototype in noce in chapters 7 12 we analyze several algorithms under the presence of computational errors which were not considered in noce again each step of an iteration has a computational errors and we take into account that these errors are in general different an optimization problems with a composite objective function is studied in chapter 7 a zero sum game with two players is considered in chapter 8 a predicted decrease approximation based method is used in chapter 9 for constrained convex optimization chapter 10 is devoted to minimization of quasiconvex functions minimization of sharp weakly convex functions is discussed in chapter 11 chapter 12 is devoted to a generalized projected subgradient method for minimization of a convex function over a set which is not necessarily convex the book is of interest for researchers and engineers working in optimization it also can be useful in preparation courses for graduate students the main feature of the book which appeals specifically to this audience is the study of the influence of computational errors for several important optimization algorithms the book is of interest for experts in applications of optimization to engineering and economics
