proteolysis is an irreversible posttranslational modification affecting each and every protein from its biosynthesis to its degradation limited proteolysis regulates targeting and activity throughout the lifetime of proteins balancing proteolysis is therefore crucial for physiological homeostasis control mechanisms include proteolytic maturation of zymogens resulting in active proteases and the shut down of proteolysis by counteracting endogenous protease inhibitors beyond the protein level proteolytic enzymes are involved

in key decisions during development that determine life and death from single cells to adult individuals in particular we are becoming aware of the subtle role that proteases play in signaling events within proteolysis networks in which the enzymes act synergistically and form alliances in a web like fashion proteases come in different flavors at least five families of mechanistically distinct enzymes and even more inhibitor families are known to date many family members are still to be studied in detail we have learned a lot about the diversity of the about 600 proteases in the human genome and begin to understand their physiological roles in the degradome however there are still many open questions regarding their actions in pathophysiology it is in this area where the development of small molecule inhibitors as therapeutic agents is extremely promising approaching proteolysis as the most important irreversible post translational protein modification essentially requires an integrated effort of complementary research disciplines in fact proteolytic enzymes seem as diverse as the scientists working with these intriguing proteins this book reflects the efforts of many in this exciting field of research where team and network formations are essential to move ahead
