one of the most important subjects for any student of engineering to master is the behaviour of materials and structures under load the way in which they react to applied forces the deflections resulting and the stresses and strains set up in the bodies concerned are all vital considerations when designing a mechanical component such that it will not fail under predicted load during its service lifetime all the essential elements of a treatment of these topics are contained within this course of study starting with an introduction to the concepts of stress and strain shear force and bending moments and moving on to the examination of bending shear and torsion in elements such as beams cylinders shells and springs a simple treatment of complex stress and complex strain leads to a study of the theories of elastic failure and an introduction to the experimental methods of stress and strain analysis more advanced topics are dealt with in a companion volume mechanics of materials 2 each chapter contains a summary of the essential formulae which are developed in the chapter and a large number of worked examples which progress in level of difficulty as the principles are enlarged upon in addition each chapter concludes with an extensive selection of problems for solution by the student mostly examination questions from professional and academic bodies which are graded according to difficulty and furnished with answers at the end emphasis on practical learning and applications rather than theory provides the essential formulae for each individual chapter contains numerous worked examples and problems

this book covers the essential topics for a second level course in strength of materials or mechanics of materials with an emphasis on techniques that are useful for mechanical design

design typically involves an initial conceptual stage during which many options are considered at this stage quick approximate analytical methods are crucial in determining which of the initial proposals are feasible the ideal would be to get within 30 with a few lines of calculation the designer also needs to develop experience as to the kinds of features in the geometry or the loading that are most likely to lead to critical conditions with this in mind the author tries wherever possible to give a physical and even an intuitive interpretation to the problems under investigation for example students are encouraged to estimate the location of weak and strong bending axes and the resulting neutral axis of bending before performing calculations and the author discusses ways of getting good accuracy with a simple one degree of freedom rayleigh ritz approximation students are also encouraged to develop a feeling for structural deformation by performing simple experiments in their outside environment such as estimating the radius to which an initially straight bar can be bent without producing permanent deformation or convincing themselves of the dramatic difference between torsional and bending stiffness for a thin walled open beam section by trying to bend and then twist a structural steel beam by hand applied loads at one end in choosing dimensions for mechanical components designers will expect to be guided by criteria of minimum weight which with elementary calculations generally leads to a thin walled structure as an optimal solution this consideration motivates the emphasis on thin walled structures but also demands that students be introduced to the limits imposed by structural instability emphasis is also placed on the effect of manufacturing errors on such highly designed structures for example the effect of load misalignment on a beam with a large ratio between principal stiffness and the large magnification of initial alignment or loading errors in a strut below but not too far below the buckling load additional material can be found on [extras.springer.com](#)
