rock rheology governs the deformation of rocks in reaction to forces within the earth's  
interior rheology is the scientific study of material properties specifically focusing on the  
relationship between stress force per unit area and strain rate rate of deformation with the  
emergence of plate tectonics it has become clear that comprehending the movement of  
plates alone is not enough to properly explain the interaction between earth's lithosphere  
and mantle convection as well as other driving forces this is apparent when analyzing the  
intricate deformation patterns of plate boundary zones which can now be accurately  
traced using space geodetic methods the rheology of rocks is influenced by various  
factors such as mineralogy geofluid composition and content grain size of minerals  
amount of melt present temperature pressure and the circumstances of differential stress  
the variation in mineralogical and chemical composition of rocks is vast and our  
understanding of crucial factors such regional heat movement and tectonic pressures is  
expanding over time the convective pattern in the upper mantle under the tectonic plates  
is not directly linked to the plate boundaries instead it could be identified and studied by  
analyzing geophysical parameters like topography gravity's wave dispersion heat flux etc  
nevertheless earthquakes are now the sole means of directly observing motions occurring  
below the earth's surface at depths exceeding a few kilometers the correlation between  
the depths at which these earthquakes occur and the speeds at which subduction takes  
place indicates that the occurrence of seismic activity is influenced by various  
parameters like temperature in this research topic we seek to comprehend the factors that  
differentiate the seismic movement of certain faults from the creeping movement of  
others what are the first causes of faults and how do they progress into plate boundaries  
the mapping of geofluids has allowed for the identification of areas that have  
experienced significant tectonic activity essentially places with active tectonic activity  
and geofluids will continue to experience earthquakes until major global geodynamic  
events change the current state of tectonic activity this research topic attempts to present  
the most advanced studies on the mechanisms of earthquakes using geophysical  
geochemical geodetic and statistical methods the focus is on understanding the entire  
process from the initial nucleation to the occurrence of the earthquake recent meetings  
held by the asia oceania geosciences society the european geosciences union the  
american geophysical union etc underlined the crucial importance of observatory  
networks of monitoring systems from space ground and subsurface based on multiple

kind of sensors of potential anomalies related to the inter seismic pre seismic co post seismic processes and their spatial and temporal scales of advances in numerical modelling of the physical processes of nucleation dynamic rupturing and seismic wave propagating of earthquakes based on coupling of multiple disciplinary observation data and of possible further researches related to the occurrence of great earthquakes and of induced seismicity
