the problem of solving complex engineering problems has always been a major topic in all industrial fields such as aerospace civil and mechanical engineering the use of numerical methods has increased exponentially in the last few years due to modern computers in the field of structural mechanics moreover a wide range of numerical methods have been presented in the literature for solving such problems structural mechanics problems are dealt with using partial differential systems of equations that might be solved by following the two main classes of methods domain decomposition methods or the so called finite element methods and mesh free methods where no decomposition is carried out both methodologies discretize a partial differential system into a set of algebraic equations that can be easily solved by computer implementation the aim of the present special issue is to present a collection of recent works on these themes and a comparison of the novel advancements of both worlds in structural mechanics applications

i entire functions of several complex variables constitute an important and original chapter in complex analysis the study is often motivated by certain applications to specific problems in other areas of mathematics partial differential equations via the fourier laplace transformation and convolution operators analytic number theory and problems of transcendence or approximation theory just to name a few what is important for these applications is to find solutions which satisfy certain growth conditions the specific problem defines inherently a growth scale and one seeks a solution of the problem which satisfies certain growth conditions on this scale and sometimes solutions of minimal asymptotic growth or optimal solutions in some sense for one complex variable the study of solutions with growth conditions forms the core of the classical theory of entire functions and historically the relationship between the number of zeros of an entire function $f(z)$ of one complex variable and the growth of $|f(z)|$ or equivalently $\log |f(z)|$ was the first example of a systematic study of growth conditions in a general setting problems with growth conditions on the solutions demand much more precise information than existence theorems the correspondence between two scales of growth can be interpreted often as a correspondence between families of bounded sets in certain frechet spaces however for applications it is of utmost importance to develop precise and explicit representations of the solutions

this introductory graduate level text provides a relatively quick path to a special topic in classical differential geometry principal bundles while the topic of principal bundles in differential geometry has become classic even standard material in the modern graduate mathematics curriculum the unique approach taken in this text presents the material in a way that is intuitive for both students of mathematics and of physics the goal of this book is to present important modern geometric ideas in a form readily accessible to students and researchers in both the physics and mathematics communities providing each with an understanding and appreciation of the language and ideas of the other
