system designers computer scientists and engineers have continuously invented and employed notations for modeling specifying simulating documenting communicating teaching verifying and controlling the designs of digital systems initially these systems were represented via electronic and fabrication details following c. e. shannon's revelation of 1948 logic diagrams and boolean equations were used to represent digital systems in a fashion that de-emphasized electronic and fabrication detail while revealing logical behavior a small number of circuits were made available to remove the abstraction of these representations when it was desirable to do so as system complexity grew block diagrams timing charts sequence charts and other graphic and symbolic notations were found to be useful in summarizing the gross features of a system and describing how it operated in addition it always seemed necessary or appropriate to augment these documents with lengthy verbal descriptions in a natural language while each notation was and still is a perfectly valid means of expressing a design lack of standardization conciseness and formal definitions interfered with communication and the understanding between groups of people using different notations this problem was recognized early and formal languages began to evolve in the 1950s when it was discovered that flip flop input equations were equivalent to a register transfer equation and that xor-like notation expanding these concepts were developed a notation that became known as a register transfer language rtl

cyber physical systems are the natural extension of the so called internet of things they are systems of collaborating computational elements controlling physical entities cyber physical systems of systems cpsos are considered the next computing revolution after mainframe computing 60 s 70 s desktop computing internet 80 s 90 s and ubiquitous computing 00 s because all aspects of daily life are rapidly evolving towards humans interacting amongst themselves as well as their environment via computational devices often mobile and because in most cases systems will employ their computational capabilities to interact amongst themselves cpsos enable the physical world to merge with the cyber one using

sensors the embedded systems monitor and collect data from physical processes such as the steering of a vehicle energy consumption or human health functions the systems are networked making the data globally available cpsos make it possible for software applications to directly interact with events in the physical world for example to measure and react to changes in blood pressure or peaks in energy consumption embedded hardware and software systems crucially expand the functionality and competitiveness of vehicles aircraft medical equipment production plants and household appliances connecting these systems to a virtual environment of globally networked services and information systems opens completely new areas of innovation and novel business platforms future cpsos will have many sophisticated interconnected parts that must instantaneously exchange parse and act on detailed data in a highly coordinated manner continued advances in science and engineering will be necessary to enable advances in design and development of these complex systems

this book presents the technical program of the international embedded systems symposium iess 2009 timely topics techniques and trends in embedded system design are covered by the chapters in this volume including modelling simulation verification test scheduling platforms and processors particular emphasis is paid to automotive systems and wireless sensor networks sets of actual case studies in the area of embedded system design are also included over recent years embedded systems have gained an enormous amount of processing power and functionality and now enter numerous application areas due to the fact that many of the formerly external components can now be integrated into a single system on chip this tendency has resulted in a dramatic reduction in the size and cost of embedded systems as a unique technology the design of embedded systems is an essential element of many innovations embedded systems meet their performance goals including real time constraints through a combination of special purpose hardware and software components tailored to the system requirements both the development of new features and the reuse of existing intellectual property components are essential to keeping up with ever more demanding customer requirements furthermore design complexities are steadily growing with an increasing number of components that have to cooperate properly embedded system designers have to cope with multiple goals and constraints simultaneously including timing power reliability dependability maintenance packaging and last but not least price

in the mid 1960s when a single chip contained an average of 50 transistors gordon moore observed that integrated circuits were doubling in complexity every year in an influential article published by electronics magazine in 1965 moore predicted that this trend would continue for the next 10 years despite being criticized for its unrealistic optimism moore's prediction has remained valid for far longer than even he imagined today chips built using state the art techniques typically contain several million transistors the advances in fabrication technology that have supported moore's law for four decades have fuelled the computer revolution however this exponential increase in transistor density poses new

design challenges to engineers and computer scientists alike new techniques for managing complexity must be developed if circuits are to take full advantage of the vast numbers of transistors available in this monograph we investigate both i the design of high level languages for hardware description and ii techniques involved in translating these hi level languages to silicon we propose safl a st order functional language designed specifically for behavioral hardware description and describe the implementation of its associated silicon compiler we show that the high level properties of safl allow one to exploit program analyses and optimizations that are not employed in existing synthesis systems furthermore since safl fully abstracts the low level details of the implementation technology we show how it can be compiled to a range of different design styles including fully synchronous design and globally asynchronous locally synchronous gals circuits
