the problem of solving complex engineering problems has always been a major topic in all industrial fields such as aerospace civil and mechanical engineering the use of numerical methods has increased exponentially in the last few years due to modern computers in the field of structural mechanics moreover a wide range of numerical methods have been presented in the literature for solving such problems structural mechanics problems are dealt with using partial differential systems of equations that might be solved by following the two main classes of methods domain decomposition methods or the so called finite element methods and mesh free methods where no decomposition is carried out both methodologies discretize a partial differential system into a set of algebraic equations that can be easily solved by computer implementation the aim of the present special issue is to present a collection of recent works on these themes and a comparison of the novel advancements of both worlds in structural mechanics applications

this text provides an accessible self contained and rigorous introduction to complex analysis and differential equations topics covered include holomorphic functions fourier series ordinary and partial differential equations the text is divided into two parts part one focuses on complex analysis and part two on differential equations each part can be read independently so in essence this text offers two books in one in the second part of the book some emphasis is given to the application of complex analysis to differential equations half of the book consists of approximately 200 worked out problems carefully prepared for each part of theory plus 200 exercises of variable levels of difficulty tailored to any course giving the first introduction to complex analysis or differential equations this text assumes only a basic knowledge of linear algebra and differential and integral calculus moreover the large number of examples worked out problems and exercises makes this the ideal book for independent study

entire functions of several complex variables constitute an important and original chapter in complex analysis the study is often motivated by certain applications to specific problems in other areas of mathematics partial differential equations via the fourier laplace transformation and convolution operators analytic number theory and problems of transcendence or

approximation theory just to name a few what is important for these applications is to find solutions which satisfy certain growth conditions the specific problem defines inherently a growth scale and one seeks a solution of the problem which satisfies certain growth conditions on this scale and sometimes solutions of minimal asymptotic growth or optimal solutions in some sense for one complex variable the study of solutions with growth conditions forms the core of the classical theory of entire functions and historically the relationship between the number of zeros of an entire function $f(z)$ of one complex variable and the growth of $f(z)$ or equivalently $\log f(z)$ was the first example of a systematic study of growth conditions in a general setting problems with growth conditions on the solutions demand much more precise information than existence theorems the correspondence between two scales of growth can be interpreted often as a correspondence between families of bounded sets in certain Frechet spaces however for applications it is of utmost importance to develop precise and explicit representations of the solutions
