an important open research topic today is to understand the relevance that dark matter halo substructure may have for dark matter searches in the

standard cosmological model halo substructure or subhalos are predicted to be largely abundant inside larger halos for example galaxies such as ours and are thought to form first and later merge to form larger structures dwarf satellite galaxies the most massive exponents of halo substructure in our own galaxy are already known to be excellent targets for dark matter searches and indeed they are constantly scrutinized by current gamma ray experiments in the search for dark matter signals lighter subhalos not massive enough to have a visible counterpart of stars and gas may be good targets as well given their typical abundances and distances in addition the clumpy distribution of subhalos residing in larger halos may boost the dark matter signals considerably in an era in which gamma ray experiments possess for the first time the exciting potential to put to test the preferred dark matter particle theories a profound knowledge of dark matter astrophysical targets and scenarios is mandatory should we aim for accurate predictions of dark matter induced fluxes for investing significant telescope observing time on selected targets and for deriving robust conclusions from our dark matter search efforts in this regard a precise characterization of the statistical and structural properties of subhalos becomes critical in this special issue we aim to summarize where we stand today on our knowledge of the different aspects of the dark matter halo substructure to identify what are the remaining big questions and how we could address these and by doing so to find new avenues for research
