entire functions of several complex variables constitute an important and original chapter in complex analysis the study is often motivated by certain applications to specific problems in other areas of mathematics partial differential equations via the fourier laplace transformation and convolution operators analytic number theory and problems of transcendence or approximation theory just to name a few what is important for these applications is to find solutions which satisfy certain growth conditions the specific problem defines inherently a growth scale and one seeks a solution of the problem which satisfies certain growth conditions on this scale and sometimes solutions of minimal asymptotic growth or optimal solutions in some sense for one complex variable the study of solutions with growth conditions forms the core of the classical theory of entire functions and historically the relationship between the number of zeros of an entire function  $f(z)$  of one complex variable and the growth of  $f(z)$  or equivalently  $\log f(z)$  was the first example of a systematic study of growth conditions in a general setting problems with growth conditions on the solutions demand much more precise information than existence theorems the correspondence between two scales of growth can be interpreted often as a correspondence between families of bounded sets in certain frechet spaces however for applications it is of utmost importance to develop precise and explicit representations of the solutions
