the first three chapters contain the elements of the theory of dynamical systems and the numerical solution of initial value problems in the remaining chapters numerical methods are formulated as dynamical systems and the convergence and stability properties of the methods are examined

over the last four decades there has been extensive development in the theory of dynamical systems this book aims at a wide audience where the first four chapters have been used for an undergraduate course in dynamical systems material from the last two chapters and from the appendices has been used quite a lot for master and phd courses all chapters are concluded by an exercise section the book is also directed towards researchers where one of the challenges is to help applied researchers acquire background for a better understanding of the data that computer simulation or experiment may provide them with the development of the theory

in recent years there has been an explosion of research centred on the appearance of so called chaotic behaviour this book provides a largely self contained introduction to the mathematical structures underlying models of systems whose state changes with time and which therefore may exhibit this sort of behaviour the early part of this book is based on lectures given at the university of london and covers the background to dynamical systems the fundamental properties of such systems the local bifurcation theory of flows and diffeomorphisms anosov automorphism the horseshoe diffeomorphism and the logistic map and area preserving planar maps the authors then go on to consider current research in this field such as the perturbation of area preserving maps of the plane and the cylinder this book which has a great number of worked examples and exercises many with hints and over 200 figures will be a valuable first textbook to both senior undergraduates and postgraduate students in mathematics physics engineering and other areas in which the notions of qualitative dynamics are employed

this textbook introduces the language and the techniques of the theory of dynamical systems of finite dimension for an audience of physicists engineers and mathematicians at the beginning of graduation author addresses geometric measure and computational aspects of the theory of dynamical systems some freedom is used in the more formal aspects using only proofs when there is an algorithmic advantage or because a result is simple and powerful the first part is an introductory course on dynamical systems theory it can be taught at the master s level during one semester not requiring specialized mathematical training in the second part the author describes some applications of the theory of dynamical systems topics often appear in modern dynamical systems and complexity theories such as singular perturbation theory delayed equations cellular automata fractal sets maps of the complex plane and stochastic iterations of function systems are briefly explored for advanced students the author also explores applications in mechanics electromagnetism celestial mechanics nonlinear control theory and macroeconomy a set of problems consolidating the knowledge of the different subjects including more elaborated exercises are provided for all chapters

chaos is the idea that a system will produce very different long term behaviors when the initial conditions are perturbed only slightly chaos is used for novel time or energy critical interdisciplinary applications examples include high performance circuits and devices liquid mixing chemical reactions biological systems crisis management secure information processing and critical decision making in politics economics as well as military applications etc this book presents the latest investigations in the theory of chaotic systems and their dynamics the book covers some theoretical aspects of the subject arising in the study of both discrete and continuous time chaotic dynamical systems this book presents the state of the art of the more advanced studies of chaotic dynamical systems

this introduction to dynamical systems theory guides readers through theory via example and the graphical matlab interface the simulink accessory is used to simulate real world dynamical processes examples included are from mechanics electrical circuits economics population dynamics epidemiology nonlinear optics materials science and neural networks the book contains over 330 illustrations 300

examples and exercises with solutions

regularity and complexity in dynamical systems describes periodic and chaotic behaviors in dynamical systems including continuous discrete impulsive discontinuous and switching systems in traditional analysis the periodic and chaotic behaviors in continuous nonlinear dynamical systems were extensively discussed even if unsolved in recent years there has been an increasing amount of interest in periodic and chaotic behaviors in discontinuous dynamical systems because such dynamical systems are prevalent in engineering usually the smoothening of discontinuous dynamical system is adopted in order to use the theory of continuous dynamical systems however such technique cannot provide suitable results in such discontinuous systems in this book an alternative way is presented to discuss the periodic and chaotic behaviors in discontinuous dynamical systems

at the end of the nineteenth century lyapunov and poincaré developed the so called qualitative theory of differential equations and introduced geometric topological considerations which have led to the concept of dynamical systems in its present abstract form this concept goes back to g d birkhoff this is also the starting point of chapter 1 of this book in which uncontrolled and controlled time continuous and time discrete systems are investigated controlled dynamical systems could be considered as dynamical systems in the strong sense if the controls were incorporated into the state space we however adapt the conventional treatment of controlled systems as

in control theory we are mainly interested in the question of controllability of dynamical systems into equilibrium states in the non autonomous time discrete case we also consider the problem of stabilization we conclude with chaotic behavior of autonomous time discrete systems and actual real world applications

this book is about dynamical aspects of ordinary differential equations and the relations between dynamical systems and certain fields outside pure mathematics a prominent role is played by the structure theory of linear operators on finite dimensional vector spaces the authors have included a self contained treatment of that subject

introduction to dynamical systems and geometric mechanics provides a comprehensive tour of two fields that are intimately entwined dynamical systems is the study of the behavior of physical systems that may be described by a set of nonlinear first order ordinary differential equations in euclidean space whereas geometric mechanics explore similar systems that instead evolve on differentiable manifolds the first part discusses the linearization and stability of trajectories and fixed points invariant manifold theory periodic orbits poincaré maps floquet theory the poincaré bendixson theorem bifurcations and chaos the second part of the book begins with a self contained chapter on differential geometry that introduces notions of manifolds mappings vector fields the jacobi lie bracket and differential forms

this book comprises an impressive collection of problems that cover a variety of carefully selected topics on the core of the theory of dynamical systems aimed at the graduate upper undergraduate level the emphasis is on dynamical systems with discrete time in addition to the basic theory the topics include topological low dimensional hyperbolic and symbolic dynamics as well as basic ergodic theory as in other areas of mathematics one can gain the first working knowledge of a topic by solving selected problems it is rare to find large collections of problems in an advanced field of study much less to discover accompanying detailed solutions this text fills a gap and can be used as a strong companion to an analogous dynamical systems textbook such as the authors own dynamical systems universitext

springer or another text designed for a one or two semester advanced undergraduate graduate course the book is also intended for independent study problems often begin with specific cases and then move on to general results following a natural path of learning they are also well graded in terms of increasing the challenge to the reader anyone who works through the theory and problems in part i will have acquired the background and techniques needed to do advanced studies in this area part ii includes complete solutions to every problem given in part i with each conveniently restated beyond basic prerequisites from linear algebra differential and integral calculus and complex analysis and topology in each chapter the authors recall the notions and results without proofs that are necessary to treat the challenges set for that chapter thus making the text self contained

dynamics reported reports on recent developments in dynamical systems dynamical systems of course originated from ordinary differential equations today dynamical systems cover a much larger area including dynamical processes described by functional and integral equations by partial and stochastic differential equations etc dynamical systems have involved remarkably in recent years a wealth of new phenomena new ideas and new techniques are proving to be of considerable interest to scientists in rather different fields it is not surprising that thousands of publications on the theory itself and on its various applications are appearing dynamics reported presents carefully written articles on major subjects in dynamical systems and their applications addressed not only to specialists but also to a broader range of readers including graduate students topics are advanced while detailed exposition of ideas restriction to typical result rather than the most general ones and last but not least lucid proofs help to gain the utmost degree of clarity it is hoped that dynamics reported will be useful for those entering the field and will stimulate an exchange of ideas among those working in dynamical systems

world scientific series in applicable analysis wssiaa aims at reporting new developments of high mathematical standard and current interest each volume in the series shall be devoted to the mathematical analysis that has been applied or potentially applicable to the

solutions of scientific engineering and social problems for the past twenty five years there has been an explosion of interest in the study of nonlinear dynamical systems mathematical techniques developed during this period have been applied to important nonlinear problems ranging from physics and chemistry to ecology and economics all these developments have made dynamical systems theory an important and attractive branch of mathematics to scientists in many disciplines this rich mathematical subject has been partially represented in this collection of 45 papers by some of the leading researchers in the area this volume contains 45 state of art articles on the mathematical theory of dynamical systems by leading researchers it is hoped that this collection will lead new direction in this field

symmetries in dynamical systems kam theory and other perturbation theories infinite dimensional systems time series analysis and numerical continuation and bifurcation analysis were the main topics of the december 1995 dynamical systems conference held in groningen in honour of johann bernoulli they now form the core of this work which seeks to present the state of the art in various branches of the theory of dynamical systems a number of articles have a survey character whereas others deal with recent results in current research it contains interesting material for all members of the dynamical systems community ranging from geometric and analytic aspects from a mathematical point of view to applications in various sciences

this book discusses continuous and discrete nonlinear systems in systematic and sequential approaches the unique feature of the book is

its mathematical theories on flow bifurcations nonlinear oscillations lie symmetry analysis of nonlinear systems chaos theory routes to chaos and multistable coexisting attractors the logically structured content and sequential orientation provide readers with a global overview of the topic a systematic mathematical approach has been adopted featuring a multitude of detailed worked out examples alongside comprehensive exercises the book is useful for courses in dynamical systems and chaos and nonlinear dynamics for advanced undergraduate graduate and research students in mathematics physics and engineering the second edition of the book is thoroughly revised and includes several new topics center manifold reduction quasi periodic oscillations bogdanov takens periodbubbling and neimark sacker bifurcations and dynamics on circle the organized structures in bi parameter plane for transitional and chaotic regimes are new active research interest and explored thoroughly the connections of complex chaotic attractors with fractals cascades are explored in many physical systems chaotic attractors may attain multiple scaling factors and show scale invariance property finally the ideas of multifractals and global spectrum for quantifying inhomogeneous chaotic attractors are discussed

the carleman linearization has become a new powerful tool in the study of nonlinear dynamical systems nevertheless there is the general lack of familiarity with the carleman embedding technique among those working in the field of nonlinear models this book provides a systematic presentation of the carleman linearization its generalizations and applications it also includes a review of existing alternative methods for linearization of nonlinear dynamical systems there are probably no books covering such a wide spectrum of linearization algorithms this book also gives a comprehensive introduction to the kronecker product of matrices whereas most books deal with it only superficially the kronecker product of matrices plays an important role in mathematics and in applications found in theoretical physics

this book is an essentially self contained introduction to topological dynamics and ergodic theory it is divided into a number of relatively short chapters with the intention that each may be used as a component of a lecture course tailored to the particular audience parts of the book are suitable for a final year undergraduate course or for a masters level course a number of applications are given principally to

number theory and arithmetic progressions through van der waerden s theorem and szemerdi s theorem

an introduction to aspects of the theory of dynamical systems based on extensions of liapunov s direct method the main ideas and structure for the theory are presented for difference equations and for the analogous theory for ordinary differential equations and retarded functional differential equations
