provide models that could be used by do it yourselfers and also can be used to provide understanding of the background issues so that one can do a better job of working with the proprietary algorithms of the software vendors in this book we strive to provide models that capture many of the tails faced by rms operating in a modern supply chain but we stop short of proposing models for economic analysis of the entire multi player chain in other words we produce models that are useful for planning within a supply chain rather than models for planning the supply chain the usefulness of the models is enhanced greatly by the fact that they have been implemented in computer modeling languages implementations are shown in chapter 7 which allows solutions to be found using a computer a reasonable question is why write the book now it is a combination of opportunities that have recently become available the availability of modeling languages and computers that provide the opportunity to make practical use of the models that we develop meanwhile software

automated planning is known to be computationally hard in the general case propositional planning is PSPACE complete and first order planning is undecidable one method for analyzing the computational complexity of planning is to study restricted subsets of planning instances with the aim of differentiating instances with varying complexity we use this methodology for studying the computational complexity of planning finding new tractable i.e. polynomial time solvable problems has been a particularly important goal for researchers in the area the reason behind this is not only to differentiate between easy and hard planning instances but also to use polynomial time solvable instances in order to construct better heuristic functions and improve planners we identify a new class of tractable cost optimal planning instances by restricting the causal graph we study the computational complexity of oversubscription planning such as the net benefit problem under various restrictions and reveal strong connections with classical planning inspired by this we present a method for compiling oversubscription planning problems into the ordinary plan existence problem we further study the parameterized complexity of cost optimal and net benefit planning under the same restrictions and show that the choice of numeric domain for the action costs has a great impact on the parameterized complexity we finally consider the parameterized complexity of certain problems related to partial order planning in some applications less restricted plans than total order plans are needed therefore a partial order plan is being used instead when dealing with partial order plans one important question is how to achieve optimal partial order plans i.e. having the highest degree of freedom according to some notion of flexibility we study several optimization problems for partial order plans such as finding a minimum deordering or reordering and finding the minimum parallel execution length

this book proposes a concept of adaptive memory programming amp for grouping a number of generic optimization techniques used in combinatorial problems the same common features seen in the use of memory and a local search procedure drive these emerging optimization techniques which include artificial neural networks genetic algorithms tabu search and ant systems the primary motivation for amp therefore is to group and unify all these techniques so as to enhance the computational capabilities that they offer for combinatorial problems encountered in real life in the area of production planning and control the text describes the theoretical aspects of amp together with relevant production planning and control applications it covers the techniques applications and algorithms the book has been written in such a way that it can serve as an instructional text for students and those who are taking tuition on their own the numerical examples given are first solved manually to enhance the reader s understanding of the material and that is followed by a description of the algorithms and computer results this way the student can fully follow the material the algorithms described for each application are useful to both students and practitioners in grasping how to implement similar applications in computer code using emerging optimization techniques

supply chain management concerns with the selection of strategies and methodologies to facilitate the optimal flow of material from raw material suppliers to the end users through procurement production and distribution activities implementation of a supply chain system has crucial impacts on a company s financial performance overall supply chain performance is influenced significantly by decisions taken in its production distribution p d network a complex p d planning problem integrates decisions in production transportation and warehousing as well as inventory management in order to minimise the overall system costs while ensuring all products are produced at the right quantities and distributed to the right customers at the right time this book aims to propose an integrated approach for the optimisation of complex aggregate p d planning problems to demonstrate the capability of the proposed approach in achieving the optimum solution the developed model in this book is implemented to solve a real life large scale p d planning problem
