in this study three different brackish surface water qualities which represented the water quality in the iraqi marshes were simulated and used as feed waters to run a flat sheet reverse osmosis ro membrane system the performance of three different types of the ro membrane thin film composite se cellulose acetate ce and polyamide ad under these water qualities was investigated the effect of the high and low feed water temperature 37 c and 11 c on the operation efficiency of the three ro membranes was also investigated in addition using the microfiltration mf membrane to pretreat the feed water and its effect on the performance of the ro membrane was examined the results revealed that the se membrane produced the highest permeate flux while the ad membrane produced the lowest permeate flux in all three feed waters also the elemental analyses showed that the ce membrane had the least rejection percentage from 91 1 to 99 2 but the ad membrane had the highest rejection percentage from 97 6 to 99 5 for all the existing feed water ions moreover using the mf membrane increased the permeate flux particularly of the runs conducted with a high temperature and slightly improved salt ions rejection ratios by the ro membranes additionally all membranes at the temperature of 37 c exhibited higher permeate fluxes than those of corresponding membranes at a lower temperature 11 c furthermore the main foulants from the simulated feed waters were diagnosed by using scanning electron microscope sem images and energy dispersive x ray spectroscopy edxs spectra finally fourier transform infrared spectroscopy ftir

analysis was used to identify the functional groups of the organic matter deposited on the ro membrane surfaces the sem images and eds spectra suggested that the fouled material was mainly organic matter and the major crystal deposited on the ro membrane was calcium carbonate CaCO_3 the ftir spectra of the fouled ro membranes suggested that the constituents of the fouled material included aliphatic and aromatic compounds
