the possibility of treating cancer a disease defined by genetic defects by introducing genes targeting these very alterations has led to an immense interest in gene therapy for cancer although incremental successes have been realized enthusiasm for gene therapy has declined due to an increasing number of obstacles these obstacles include vector systems that do not reach systemic metastases therapeutic genes with redundant mechanisms allowing for cellular resistance and toxicities in clinical trials leading to premature closure of these studies different tactics to overcome or circumvent these obstacles have catalyzed the development of a wide range of gene therapy approaches thus far almost two thirds of gene therapy trials have focused on cancer this reflects the concept that gene therapy approaches for the treatment of cancer do not necessarily require long term expression of the gene as is necessary for the treatment of primary genetic defects like hemophilia or juvenile diabetes unlike the treatment of genetic defects where expression of the corrected gene needs to be

strong permanent and sometimes regulated tactics to treat tumors can be based on temporary and locally limited effects in addition cancer cells have different properties than normal cells and this allows for targeting gene therapy to specific cells a major advantage over current antitumor therapies which are also toxic to normal cells and tissues
