there any differences in p selectin in plasma 3 days after admission conclusion there is a remarkably high bleeding incidence among patients treated with dapt and even more so if treated with tat female gender is an independent risk factor of inhospital bleeding after myocardial infarction this higher bleeding risk in women appears to be restricted to invasively treated patients and stemi patients even if women had higher short and long term mortality there was no difference between the genders among those who bled after multivariable adjustment the prognostic impact of bleeding complications was higher in men women seem to experience more minor minimal bleeding complications than men predominantly gi bleeding events and access site bleeding events with no apparent impact on outcome in contrast men with non surgery related bleeding complications had higher mortality there is a lack of differences between the genders concerning platelet aggregation our results do not support gender disparities in platelet reactivity and excess dosing as a major explanation for increased bleeding risk in women improved bleeding prevention strategies are warranted for both men and women
