in singapore during 2015 group b streptococcus gbs sequence type 283 st283 caused the only reported foodborne outbreak of invasive gbs disease over 20 percent of cases were healthy adults without comorbidities which is unusual for gbs the outbreak was linked to the consumption of raw freshwater fish subsequent investigations found that st283 gbs has been common among gbs causing disease in humans and in tilapia across southeast asia for at least 20 years whereas it was almost non existent outside this region given the novelty of the

outbreak this risk profile consolidates the current knowledge to identify data gaps about gbs st283 along the freshwater fish supply chain in southeast asia although gbs fish infection can present with few clinical signs of disease outbreaks of gbs in high intensity tilapia aquaculture can result in severe infection with mortalities of up to 80 percent these outbreaks are largely undocumented but likely have a wide effect on aquaculture given its economic and social importance across southeast asia there is also a lack of data on patterns of fish consumption including frequency amount preparation and consumer demographics nevertheless consumption of non heat treated freshwater fish is common in southeast asia given the multitude of data gaps the risk posed by gbs st283 from consumption of freshwater fish remains highly uncertain potential risk management options start with the application of good aquaculture practices and good food safety measures throughout the supply chain
