abstract terrain surfaces are often approximated by geometric meshes to permit efficient rendering this paper describes how the complexity of an approximating irregular mesh can be varied across its domain in order to minimise the number of displayed facets while ensuring that the rendered surface meets pre determined resolution requirements we first present a generalised scheme to represent a mesh over a continuous range of resolutions using the output from conventional single resolution approximation methods we then describe an algorithm wich extracts a surface from this representation such that the resolution of the surface is enhanced only in specific areas of interest we prove that the extracted surface is complete minimal satisfies the given resolution constraints and meets the delaunay triangulation criterion if possible in addition we present a method of performing smooth visual transitions between selectively refined meshes to permit efficient animation of a terrain scene
