howard g knuttgen of biology boston university 2 cummington department
street boston 02215 massachusetts usa the relationship of the formation of
lactate acid to skeletal muscle energy release in exercising humans was first
explored by a v hill and co workers 21 22 the term oxygen debt was
suggested by them to describe the excess oxygen consumption of recovery
which they felt was closely related a combination of their work and the earlier
work of krogh and lindhard 35 resulted at that time in the belief that a
certain amount of energy release during the transition from rest to exercise
was provided by a non aerobic source glycolysis the resulting accumulation
of lactic acid as lactate in the body required an extra consumption during

recovery for its oxidative removal jervell 24 subsequently showed that in exercise the greatest accumulation in blood took place during the first few minutes he felt that the blood lactate increase was due to a shortage of oxygen during the transition period the observation was also made for the first time that the increased level of lac tate due to exercise could be made to fall faster if mild exercise was employed by the subjects in place of sedentary recovery the work of margaria edwards and dill 40 appeared in 1933 they observed that exercise treadmill running could be carried on at low levels without significant changes in resting levels of blood lactate
