recent years have seen silicon integrated circuits enter into an increasing number of technical and consumer applications until they now affect everyday life as well as technical areas polycrystalline silicon has been an important component of silicon technology for nearly two decades being used first in mos integrated circuits and now becoming pervasive in bipolar circuits as well during this time a great deal of information has been published about polysilicon a wide range of deposition conditions has

been used to form films exhibiting markedly different properties seemingly contradictory results can often be explained by considering the details of the structure formed this monograph is an attempt to synthesize much of the available knowledge about polysilicon it represents an effort to interrelate the deposition properties and applications of polysilicon so that it can be used most effectively to enhance device and integrated circuit performance as device performance improves however some of the properties of polysilicon are beginning to restrict the overall performance of integrated circuits and the basic limitations of the properties of polysilicon also need to be better understood to minimize potential degradation of circuit behavior

in the summer of 1981 i was asked to consider the possibility of manufacturing a 600 000 transistor microprocessor in 1985 it was clear that the technology would only be capable of manufacturing 100 000 200 000 transistor chips with acceptable yields the control store rom occupied approximately half of the chip area so i considered adding spare rows and columns to increase rom yield laser programmed polysilicon fuses would be used to switch between good and bad circuits since only half the chip area

would have redundancy i was concerned that the increase in yield would not outweigh the increased costs of testing and redundancy programming the fabrication technology did not yet exist so i was unable to experimentally verify the benefits of redundancy when the technology did become available it would be too late in the development schedule to spend time running test chips the yield analysis had to be done analytically or by simulation analytic yield analysis techniques did not offer sufficient accuracy for dealing with complex structures the simulation techniques then available were very labor intensive and seemed more suitable for redundant memories and other very regular structures stapper 80j i wanted a simulator that would allow me to evaluate the yield of arbitrary redundant layouts hence i termed such a simulator a layout or yield simulator since i was unable to convince anyone to build such a simulator for me i embarked on the research myself
