the 12 chapters in the second section contain nearly all of the tests and assessment techniques covered in the previous editions plus many additional ones including newly developed neuropsychological tests tests from other branches of psychology research techniques that have only recently been introduced into clinical neuropsychology tests originating in europe and elsewhere and a few measures as yet untried by neuropsychology that appear to be potentially useful for neuropsychological purposes thus the third edition of neuropsychological assessment maintains its multipurpose functions as an authoritative

the corpus callosum is one of several brain structures particularly affected in children with heavy prenatal alcohol exposure although the majority of children with fetal alcohol syndrome *fas* do not have agenesis or absence of the corpus callosum the rate of callosal agenesis in *fas* is higher than in the general population or other developmentally disabled populations there is also evidence that among alcohol exposed children who do have a corpus callosum overall callosal area is reduced particularly in the anterior and posterior regions a recent study assessing corpus callosum functioning in alcohol exposed children without any indication of callosal agenesis found that alcohol exposed children made more errors on a finger localization task when information had to cross the corpus callosum and these increased errors correlated significantly with anterior and posterior corpus callosum areas these data suggest that interhemispheric transfer is impaired in alcohol exposed children however it is unclear how alcohol exposed children will perform on other tasks requiring integrity of the corpus callosum and specifically on tasks that require interaction between the two cerebral hemispheres goals of this study were to examine how alcohol exposed children perform on tasks measuring 1 interhemispheric interaction 2 interhemispheric transfer of tactual teaming and 3 bimanual coordination in general on these tasks children with histories of heavy prenatal alcohol exposure *alc* demonstrated poorer performance overall compared to normally developing control *nc* children for mildly

difficult tasks and children were able to integrate information and transfer newly learned information across the cerebral hemispheres as well as normal children neither alcohol-exposed nor normal children were able to effectively integrate or transfer information across the hemispheres as tasks increased in complexity on a test of bimanual coordination alcohol-exposed children were slower than normal children with respect to basic visuomotor ability and were less accurate when the task was particularly reliant on interhemispheric interaction these findings indicate that disruption of corpus callosum functioning in alcohol-exposed children is likely to be subtle in nature and only detectable by tasks especially reliant on corpus callosum functioning
