this concise sophisticated introduction to planetary climates explains the global physical and chemical processes that determine climate on any planet or major planetary satellite from mercury to neptune and even large moons such as saturn's titan although the climates of other worlds are extremely diverse the chemical and physical processes that shape their dynamics are the same as this book makes clear the better we can understand how various planetary climates formed and evolved the better we can understand earth's climate history and future

the early development of life a fundamental question for humankind requires the presence of a suitable planetary climate our understanding of how habitable planets come to be begins with the worlds closest to home venus earth and mars differ only modestly in their mass and distance from the sun yet their current climates could scarcely be more divergent only earth has abundant liquid water venus has a runaway greenhouse and evidence for life supporting conditions on mars points to a bygone era in addition an earth like hydrologic cycle has been revealed in a surprising place saturn's cloud covered satellite titan has liquid hydrocarbon rain lakes and river networks deducing the initial conditions for these diverse worlds and unraveling how and why they diverged to their current climates is a challenge at the forefront of planetary science through the contributions of more than sixty leading experts in the field comparative climatology of terrestrial planets sets forth the foundations for this emerging new science and brings the reader to the forefront of our current understanding of atmospheric formation and climate evolution particular emphasis is given to surface atmosphere interactions evolving stellar flux mantle processes photochemistry and

this book chronicles the history of climate science and planetary exploration focusing on our ever expanding knowledge of earth's climate and the parallel research underway on some of our nearest neighbours mars venus and titan from early telescopic observation of clouds and ice caps on planetary bodies in the seventeenth century to the dawn of the space age and the first robotic planetary explorers the book presents a comprehensive chronological overview of planetary climate research right up to the dramatic recent developments in detecting and characterising exoplanets meanwhile the book also documents the discoveries about our own climate on earth not only about how it works today but also how profoundly different it has been in the past highly topical and written in an accessible and engaging narrative style this book provides invaluable historical context for students researchers professional scientists and those with a general interest in planetary climate research

not long ago the solar system was the only example of a planetary system a star and the bodies orbiting it that we knew now we know thousands of planetary systems and have even been able to observe planetary systems at the moment of their birth this very short introduction explores this new frontier incorporating the latest research the book takes the reader on a journey through the grand sweep of time from the moment galaxies begin to form after the big bang to trillions of years in the future when the universe will be a dilute soup of dim galaxies populated mostly by red dwarf stars throughout raymond t pierrehumbert introduces the latest insights gained from a new generation of telescopes that catch planetary systems at the moment of formation and to the theoretical advances that attempt to make sense of these observations he explains how the elements that make up life and the planets on which life can live are forged in the interiors of dying stars and make their way into rocky planets he also explores the vast array of newly discovered planets orbiting stars other than our own and explains the factors that determine their climates finally he reveals what determines how long planetary systems can live and what happens in their end times very short introductions brilliant sharp inspiring about the series the very short introductions series from oxford university press contains hundreds of titles in almost every subject area these pocket sized books are the perfect way to get ahead in a new subject quickly our expert authors combine facts analysis perspective new ideas and enthusiasm to make interesting and challenging topics highly readable

the three planets of the inner solar system with significant atmospheres venus earth and mars can be described as representing three climate archetypes of terrestrial planets venus is hot dry and rotates slowly mars is cold and dry with fast rotation similar to earth earth is the middle ground warm enough to sustain liquid water on its surface but not so warm it evaporates away these archetypes can be placed as endpoints on a spectrum of climates where adjusting one or more planetary parameters can move a climate from one archetype to another e g drying the surface can move an earth like planet towards the venus and mars archetypes in addition to the three inner planets there is one additional body in the solar system that has a thick atmosphere and solid surface titan a moon of saturn titan presents a unique opportunity in observable planetary climates because it has a volatile liquid or condensable on its surface in the form of methane this methane is able to evaporate to form clouds turtle et al 2018 and likely rain turtle et al 2011 but is mostly restricted to large polar lakes lunine and lorenz 2009 with the rest of the surface a vast desert mitchell and lora 2016 this means titan's climate archetype is between the ocean dominated earth and the fully dry venus mars in this dissertation we seek to further investigate the in betweens of these climate archetypes focusing on the transition between an earth like planet and a titan like one to accomplish this we recreate a titan like climate using an earth like global climate model gcm by varying a small set of planetary parameters we first limit the available water by placing a continental land strip centered on the equator and varying its

width this mimics titan s dry tropics and wet poles and could be similar to past continental arrangements in earth s history second we take three of these land strip widths and vary the rotation period starting with earth s rotation and moving towards titan s 16 earth days third for the same three land strip widths and using earth s rotation we vary the volatility of the condensable via a constant multiplied to the saturation vapor pressure titan s condensable methane is more volatile under titan s surface conditions than water is on earth resulting in high specific humidities by artificially increasing the saturation vapor pressure we can approximate this effect without changing the properties of the condensable we find that simply replicating titan s parameters in our simulations does not fully reproduce titan like conditions in addition we find that it is possible to reproduce key titan like features by varying only the width of the equatorial land strips this may indicate that there are many possible in between states an earth like planet can have that span the gap between the earth and titan climate archetypes it also suggests titan s current climate is primarily dependent on its surface liquid distribution meaning an earth like planet with similar topography is likely to display the same features
