Ca₂₊ signaling in neurons is characterized by highly restricted and dynamic gradients called Ca₂₊ waves, spikes, transients, and puffs, depending upon their corresponding spatial and temporal features. Based on this strict segmentation, the Ca₂₊ ion provides a versatile basis for complex signaling in neuronal subcompartments with a spatial resolution of micro and nanodomains. The multitude of Ca₂₊ regulated processes requires specialized downstream processing machinery translating the Ca₂₊ signal into alterations of cellular processes. The broad range of different Ca₂₊ triggered phenomena in neurons, ranging from neurotransmission to gene expression, is reflected by the existence of a multitude of different Ca₂₊ binding proteins (CaBPs), from which numerous belong to the EF-hand superfamily. EF-hand proteins can be subdivided into Ca₂₊ buffer and Ca₂₊ sensor proteins, whereas the first group has a very high affinity for Ca₂₊ and exhibits little conformational change in the Ca₂₊ bound state and is thought to mainly chelate Ca₂₊. The second group has a lower affinity for Ca₂₊ and shows considerable conformational

changes upon Ca^{2+} binding which usually triggers a target interaction. Neuronal calcium sensor (NCS) proteins and the related calmodulin-binding proteins (CaMBPs) are members of this latter group. They resemble the structure of their common ancestor, calmodulin (CaM), with four EF hand Ca^{2+} binding motifs, of which not all are functional. However, despite their structural homology with CaM, NCSs as well as CaMBPs are quite diverse in amino acid sequence. It is therefore surprising that relatively few binding partners have been identified that are not CaM targets, and this raises the question of the specificity and function of these interactions in terms of function. Binding of NCSs and CaMBPs has frequently different consequences than binding of CaM, which substantially increases the versatility of the Ca^{2+} tool kit. The general idea of this special issue is to provide an overview on the function of neuronal EF hand calcium binding proteins in health and disease, but we will not just provide a mere collection of articles to stress the function of each protein. The issue will mainly deal with emerging concepts on Ca^{2+} signaling buffering mediated by EF hand Ca^{2+} binding proteins. This includes questions like features that define the functional role of a EF hand calcium sensor in neurons, the conditions that make physiological relevance of a given interaction of a CaMBP with its target plausible, the emerging synaptic role of these proteins, and mounting evidence for their role in the regulation of protein trafficking, structural aspects and biophysical studies will be covered. Another aspect will be the role of CaMBPs in brain disease states. This aspect includes studies showing that CaMBPs are targets of drugs in clinical use, studies showing that expression levels of calcium binding proteins are frequently altered in brain disease states, as well as reports on mutations in EF hand calcium sensors linked to human disease.

New techniques for studying biomembranes describes some of the latest methods used to investigate the dynamic distribution of specific lipids in membranes and their effects on other membrane components. The contributors present important discoveries with respect to lipid analysis and lipid interactions with membrane proteins. Various methods which have been used to study lipid bilayer structure and lipid organization in membranes include both *in vitro* and *in vivo* membrane systems and study membrane proteins in various membrane systems. Key features reviews both *in vivo* and *in vitro* analytical technologies and methods for studying membrane structure and function explores how lipid bilayers and membrane proteins interact. Includes contributions from an international team of researchers actively studying membrane structure and function identifies various diseases whose causes are related to membrane proteins.
